

EXERCISE 1: READ AI-GENERATED HTML (LEVEL 1, ~25 MIN)

Send this prompt to ChatGPT:

Tag	Purpose	What It Looks Like in the Browser
<!DOCTYPE html>	document type declaration, It tells the browser: <i>"This document is written in HTML5, please render it using modern standards."</i>	Not visible — it's an instruction to the browser, not content.
<html>	The root element that wraps all content on the page. Everything else lives inside it.	Not visible, but it contains everything you see.
<head>	Container for metadata about the page — things the browser and search engines need but visitors don't see directly.	Not visible, but it contains the <title> you can see the title on the browser tab at the top
<title>	The title of the tab. Sets the name of the page.	Appears in the browser tab, in bookmarks, and in search engine results, but not on the page itself.
<body>	The body tag. Container for all visible content, the text, images, links, everything the user actually sees.	Nothing visible on its own like <body>, but it holds all the visible content of the page.
<h1>	A header tag. The main (top-level) heading of the page. Usually only one per page.	Large, bold text. It is the biggest heading by default.
<p>	A paragraph tag	You can't see the <p> tag but you can see the content inside of it: a word, sentence, or paragraph, depending on what you put in it. It has space above and below it by default

<code></code>	This tag means an unordered list — a container for list items that don't have a specific order.	You can't see the <code></code> tag, but it gives its <code></code> children bullet points by default.
<code></code>	This is a tag that lists a single list item	You can't see the tag <code></code> but it shows the content you put in it.
<code><a></code>	An anchor tag, It creates a hyperlink to another page, file, or location. It needs an href attribute. And you can use it to download something too.	It looks like an underlined text, usually blue, purple after visiting. Clicking it navigates somewhere if you included a link or a download attribute.
<code></code>	This is an image tag, it embeds an image on the page. It needs a src image file or link, and should have an alt = description for screen readers to define what the image is.	It shows the actual image. If the image can't load, the alt text shows in its place.

1. Which tag doesn't have a closing tag? Why not?
2. Image is the one without a `</img>` tag, the `<meta>` tag, the `<!DOCTYPE html>` don't have a closing tag, because they don't surround any content, they are their own thing on their own like an image for example.
3. What would happen if you deleted the `<body>` tag but kept everything inside it?

Nothing happened, when I removed the `<body>` tag right now, but you need the separation between the head and body. If later on, you later add CSS to style your page — say, giving the whole page a background color or a default font
4. If a tag is unfamiliar, ask AI: "What does the `<__>` tag do in HTML?" -- then add it to your notes.

<main> Marks the **main content** of the page — the stuff that's unique to *this specific page*, not headers, navigation, sidebars, or footers that repeat across the site.

You should only have **one <main> per page**. **Why bother?** Screen readers (used by visually impaired visitors) let users *jump straight to the main content* with a keyboard shortcut, skipping the navigation. Without <main>, they have to listen through every menu item on every page. It's also helpful for search engines figuring out what the page is actually about.

<section> tag groups related content together under a common theme, usually with its own heading. Think of it like a chapter in a book. The rule of thumb: **if you can give it a meaningful heading, it's probably a <section>**. If you're just grouping things for styling purposes with no thematic meaning, use <div> instead.

ARIA (which stands for **Accessible Rich Internet Applications**) is a set of *attributes* you add to existing tags, not a tag of its own. They start with aria- and help assistive technologies like screen readers understand your page better.

aria-label — gives an element an accessible name when there's no visible text. Useful for icon-only buttons: <button aria-label="Close

EXERCISE 2: BUILD A BASIC PAGE FROM SCRATCH IN VS CODE (LEVEL 1, ~30 MIN)

No AI for this one. Build it yourself.

EXERCISE 3: ADD CSS USING AN EXTERNAL STYLESHEET (LEVEL 2, ~35 MIN)

Step 1: In the same *week-02* folder, create a new file called *style.css*.

EXERCISE 4: FLEXBOX HEADER (LEVEL 2, ~25 MIN)

Add a header bar to your page using the flexbox pattern from lecture.

AI's Change	What It Does	My Decision (Accept / Reject / Modify)	Why
AI suggested changes to letter spacing and font-family.	Makes text easier to read	Accept	Suggested it was easier to read

Changed background color and font color.	Different font stack	Modify	Suggested it was softer color, reduces eye strain and creates more depth.
Suggested changes on h1	Changed size	Modified	Slightly larger and tighter spacing
Suggested changes on p	Changed my align content	Modified	AI said align content doesn't affect paragraphs.
Suggested to change the padding on body	Changed my padding	Modified	Reduce padding to better balance
Suggested hover effect	Provides the code to hover	Accepted	Makes is more interactive, adds a subtle polish.
Suggested I remove my hearts and put none for list style	Removed my Hearts in the new code	Accepted	Current padding: 20px is too heavy Background cards make items feel intentional Heart emoji lists can feel cluttered—consider using it sparingly or via ::before
Changed my border radius from 10px to 8px for list	Gave me an updated code	Accepted	No Comment made for the change
Suggested that pull quote variables were never	Created a :root of colors	Accepted	...but those variables are never defined.

defined: color: var(--text); background: var(--gradient);			
Added root: :root { --text: #e2e8f0; --gradient: linear-gradient(90deg, #6366f1, #60a5fa); }	Created a :root of colors. Created the code.	Accepted	...but those variables are never defined.
Suggested text-align: center; opacity: 0.95; for pull-quote-text class	Provided the new code	Accepted.	Because it centered the quote.
Suggested change site header	Provided the new code	Accepted	To make it look premium. Adds modern “glassmorphism” feel Subtle border improves separation
Change navigation spacing	Provided the new code	Accepted	Slightly tighter spacing looks cleaner Opacity adds subtle depth
Suggested change site header list	Provided the new code	Accepted	Adds shadow to depth

			Gives a layered, modern UI feel Prevents everything from looking flat
Suggested Option * {}	Provided the new code	Accepted	Smoother overall feel. Prevents layout quirks Adds subtle polish
AI didn't know about my image.	I needed to resize and center it.	NONE	I changed the image size in html with inline css
After Changing it to the light mode. I realized I liked the about me landing page much better than the dark mode.	AI removed my decorative quotes	I Modified and stayed with the light mode	I actually like it.
